Activation Functions

Sigmoid Activation Function

Sigmoid (logistic function)

$$f(x) = \frac{1}{1 + \exp(-x)}$$

$$f'(x) = f(x)(1 - f(x))$$

→ Observe that the derivative can be solely expressed in terms of the activation!

Tanh Activation Function

Tanh

$$f(x) = \tanh(x)$$

$$f'(x) = 1 - f(x)^2$$

→ The derivative is still a function of the activation!

Elman Recurrent Neural Network

General strategy

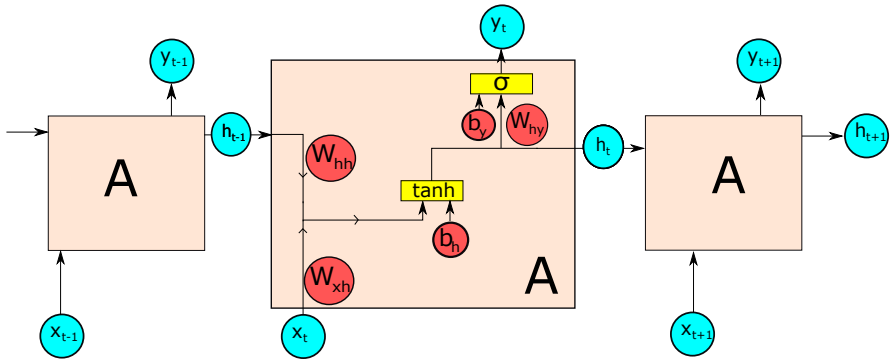

- We interpret the **batch** dimension as **time** dimension now

General strategy

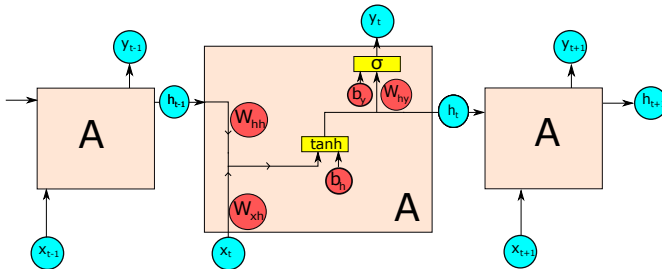

- We interpret the **batch** dimension as **time** dimension now
- Samples are correlated in this dimension

General strategy

- We interpret the **batch** dimension as **time** dimension now
- Samples are correlated in this dimension
- This allows to **reuse** loss functions, optimizers, initializers, activation functions and the Neural Network class

Elman RNN Cell

Output formula:

$$\mathbf{y}_t = \sigma (\mathbf{h}_t \cdot \mathbf{W}_{hy} + \mathbf{b}_y)$$

\mathbf{W}_{hy} : Weight matrix for current hidden state \mathbf{h}_t

\mathbf{b}_y : Output bias

A word on software engineering

- In terms of **encapsulation** - how good was the idea to demand exposition of the weights as member?

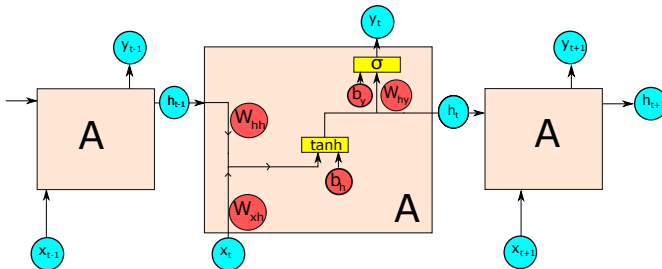

A word on software engineering

- In terms of **encapsulation** - how good was the idea to demand exposition of the weights as member?
- Suppose we implement the RNN cell as **composite** structure
- **Getters** and **Setters** provide us the flexibility to do so

A word on software engineering

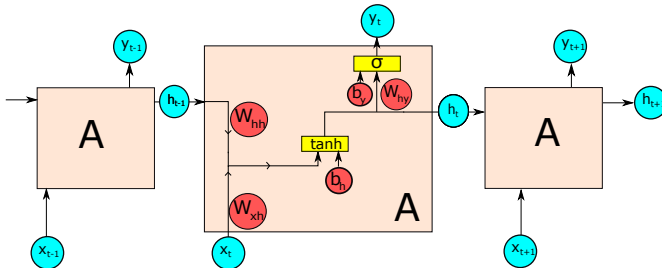

- In terms of **encapsulation** - how good was the idea to demand exposition of the weights as member?
- Suppose we implement the RNN cell as **composite** structure
- **Getters** and **Setters** provide us the flexibility to do so
- Takeaway? Not doing **proper software engineering** most of the time will demand a price at some point.

Elman RNN Cell

$$h_t = \tanh(h_{t-1} \cdot W_{hh} + x_t \cdot W_{xh} + b_h)$$

Elman RNN Cell

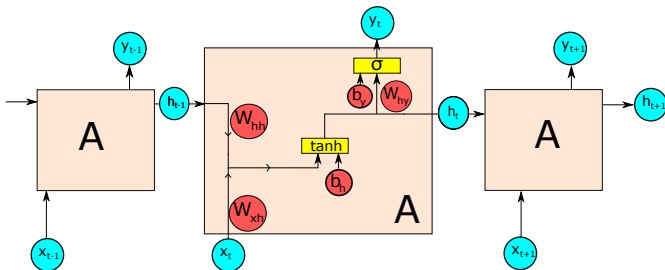

$$\mathbf{h}_t = \tanh(\mathbf{h}_{t-1} \cdot \mathbf{W}_{hh} + \mathbf{x}_t \cdot \mathbf{W}_{xh} + \mathbf{b}_h)$$

\mathbf{W}_{hh} : Weight matrix for previous hidden state \mathbf{h}_{t-1}

\mathbf{W}_{xh} : Weight matrix for current input \mathbf{x}_t

\mathbf{b}_h : Update bias

Elman RNN Cell

$$h_t = \tanh(\tilde{x}_t \cdot W_h)$$

W_h : Weight matrix of a fully connected layer

\tilde{x}_t : Concatenation of x_t , h_{t-1} and a 1

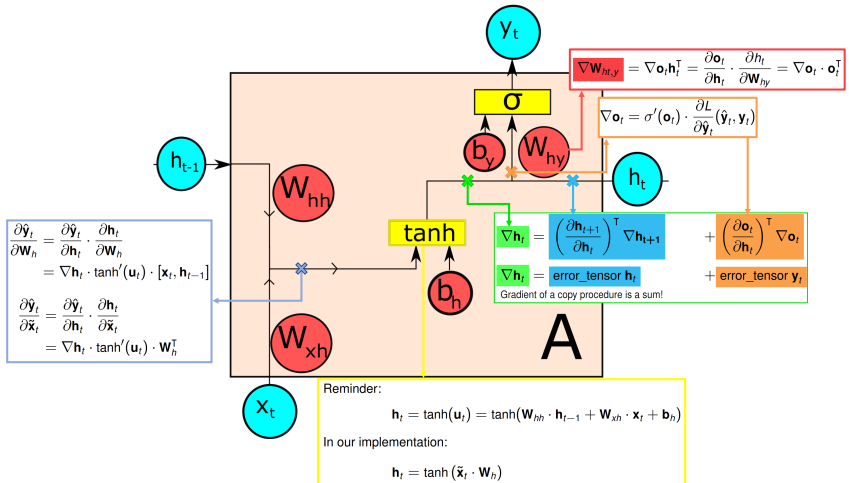

Different from output: Not processed independently!

Backward

- Most gradients are handled by the **embedded layers**
- **Store and feed the values for backprop (input tensors, activations) externally** to the embedded layers because of **multiple forward calls**
- We need gradients through **summation, multiplication and copying**

Elman RNN Cell Backward

Backward

Sum

$$f(x_1, x_2) = x_1 + x_2$$

$$\frac{\partial \hat{y}}{\partial x_1} = 1$$

Gradient is **copying** $\frac{\partial L}{\partial \hat{y}}$

Multiply

$$f(x_1, x_2) = x_1 \cdot x_2$$

$$\frac{\partial \hat{y}}{\partial x_1} = x_2$$

Gradient is \cdot with **switched inputs**

Copy

Backward pass of sum
So the gradient is a sum!

- Implemented by passing the whole sequence as a **batch**

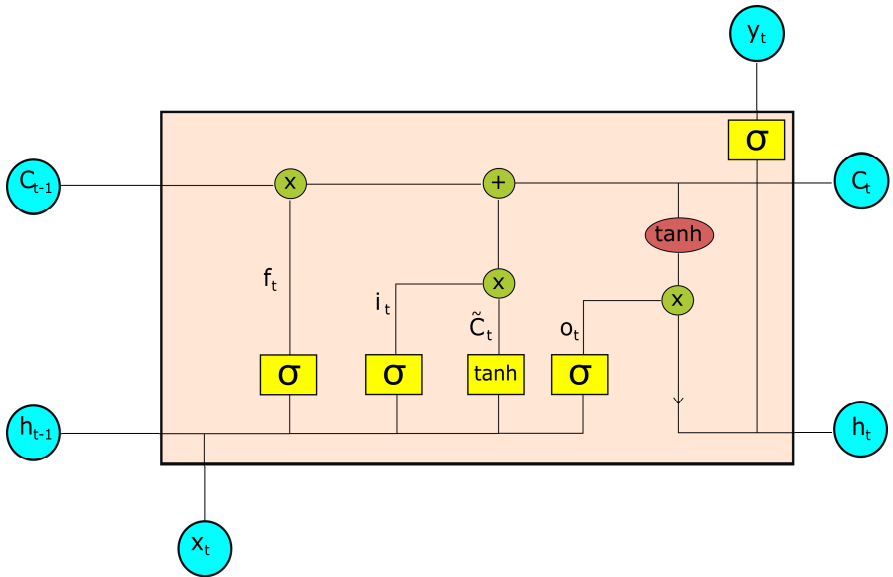

- Implemented by passing **overlapping** parts as a **batch**
- We need to implement memory **between states**
- Simply store the **last hidden state** and implement a **method** switching whether this state is reused in subsequent forward passes.
- Data has to be fed in **accordingly!**
- Referencing the TBPPT Algorithm presented in the lecture: k_1 is always the sequence length and k_2 is always the TBPTT length.

Long Short-Term Memory (optional)

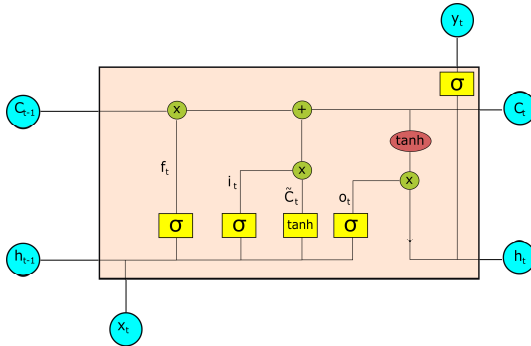

Forward

- We can reuse a **fully connected** layer again for the **output**
- Unlike in the lecture, the output gate is a trainable fully connected layer to allow different output sizes
- The **concatenation** is also **analogous** to the RNN
- The gates σ and the yellow \tanh can be a single **fully connected** layer with an output size of $4 \cdot \text{dim}(\text{hidden state})$

Backward

- Remember that we have to pass the vectors of the input tensor **sequentially**
- Most gradients are again handled by the **embedded layers**
- Again **store and feed the values for backprop externally** to the embedded layers

Thanks for listening.
Any questions?
